Live Cell Cycle Analysis of *Drosophila* Kc167 cells using Hoechst 33342 or VybrantDyeCycle Violet on the Attune Cytometer

Dec. 7\(^{th}\) 2011

Laura Buttitta
University of Michigan, MCDB Dept.

*Drosophila* Kc167 cells (https://dgrc.cgb.indiana.edu/product/View?product=1) were cultured for 24 hours in complete medium at 25\(^{o}\)C. (Schneider’s Medium Gibco #21720-024, 10% heat-inactivated FBS HyClone SH30070.03, 1X Pen-Strep Gibco #15070-063)

Cells were plated at a density of 1X10\(^{6}\) cells/mL in complete medium containing either DMSO (control) or 20 \(\mu\)M SP600125 (Sigma S5567) to increase G1 population, for 24 hours. (Note that in contrast to mammalian cells, proliferating *Drosophila* cells are primarily in G2 phase\(^{1}\)).

Cells were re-suspended by gentle pipetting (*Drosophila* Kc167 cells are semi-adherent).

100\(\mu\)L of re-suspended cells were added to 1mL of Dulbecco’s 1X PBS (Invitrogen 14190-144) containing either no dye, 10\(\mu\)L of 0.5 mg/mL Hoechst 33342 (Sigma B2261)* or 0.5\(\mu\)L of Vybrant DyeCycle Violet (Invitrogen V35003)**.

Cells were incubated at room temperature for 10 minutes.

Cells were run on the Attune cytometer using standard sensitivity at a flow rate of 100\(\mu\)L/min.

* We find that increasing the Hoechst concentration from the standard Live Drosophila cell protocol\(^{2}\) improves Hoechst 33342 detection with the Violet Attune laser excitation.

** We find that a final concentration of 0.5\(\mu\)L/mL DyeCycle Violet provides sufficient DNA staining without the toxicity to Drosophila cells we observed at higher concentrations.
